

How to read curves for NIV

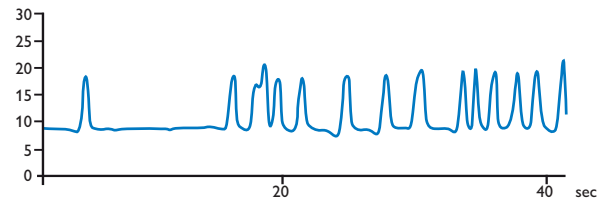

Monitoring pressure, flow and volume curves during NIV
To assess common problems

- Auto triggering
- Double triggering
- Ineffective triggering
- Leakage

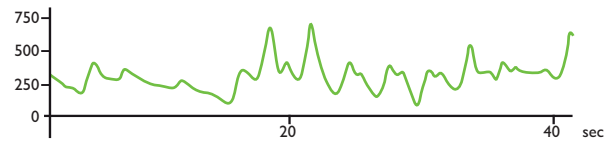

- The proposed interpretation of the proposed curves does not substitute the clinical expertise of the physician and/or respiratory therapist
- These suggestions therefore **do not** substitute the clinical judgment and decision of the physician and/or respiratory therapist

PHILIPS

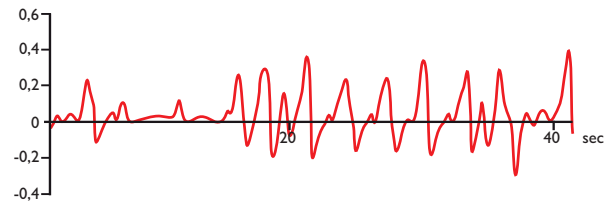

Pressure (cmH₂O)

Volume (mL)

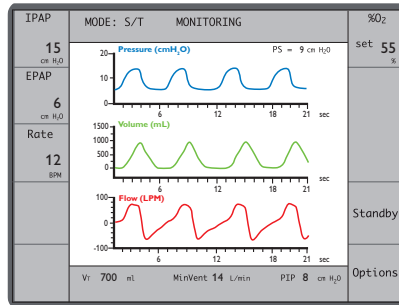

Flow (LPM)

Main troubleshooting during NIV

- Auto-triggering
- Ineffective triggering
- Double-triggering
- Leakage

▼ **Complete waveform monitoring facilitates troubleshooting**

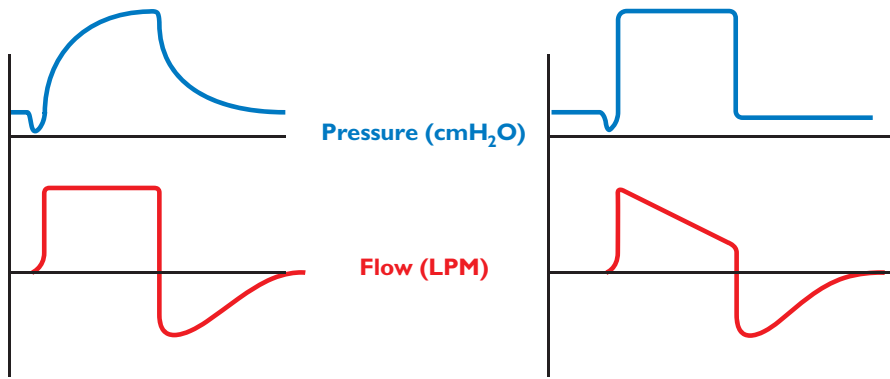

• **Pressure**

• **Volume**

• **Flow**

Two main ventilatory modes: pressure and volume mode

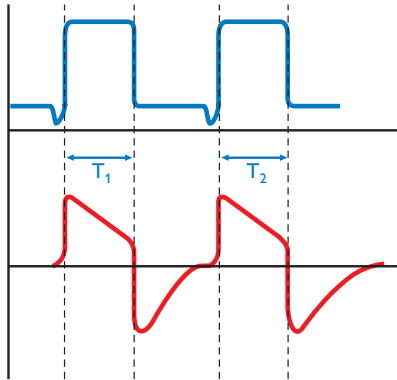

Volume mode

- Independent value is Volume
- Dependant value is Pressure

Pressure mode

- Independent value is Pressure
- Dependant value is Volume

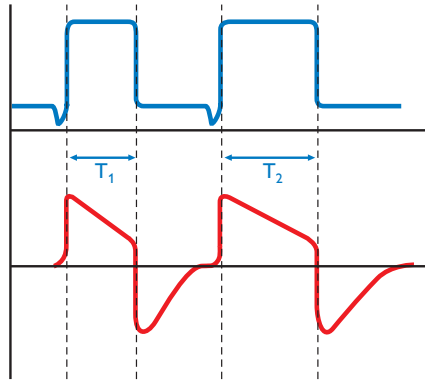

Usual pressure modes for NIV: PCV, PSV

Pressure Control Ventilation (PCV)

Fixed Inspiratory Time

$$T_1 = T_2$$

Pressure Support Ventilation (PSV)

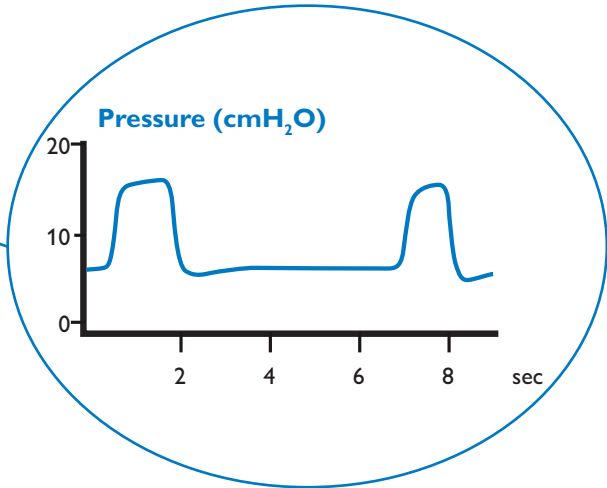

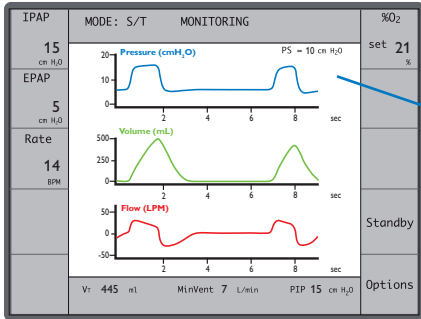

Inspiratory Time depends on patient breathing pattern

$$T_1 \neq T_2$$

NIV requirements:

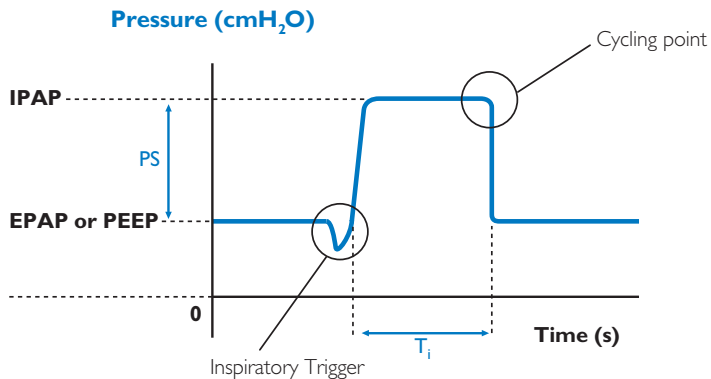

Two breaths for each of the modes

- Pressure Control Ventilation (PCV)
 - ▼ Fixed inspiratory time
- Pressure Support Ventilation (PSV)
 - ▼ Variable inspiratory times

Pressure curve

Points of interest

IPAP: Inspiratory Positive Airway Pressure

EPAP: Expiratory Positive Airway Pressure

PEEP: Positive End Expiratory Pressure

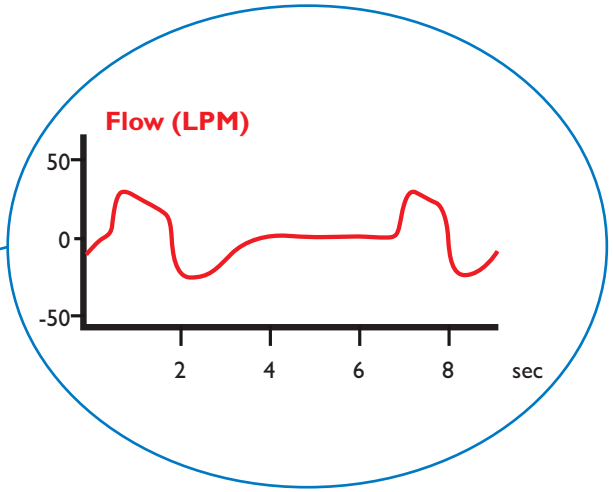

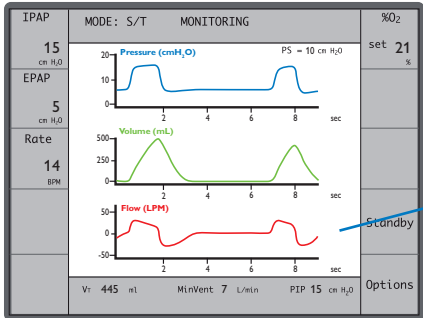

PS: Pressure support

T_i: Inspiratory time

EPAP = PEEP

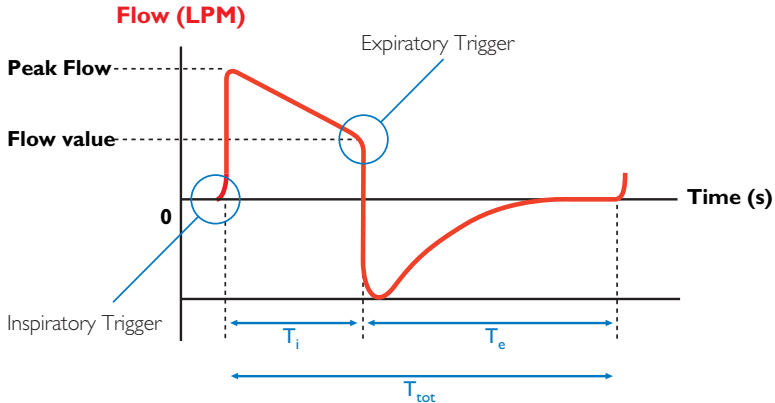

PS = IPAP - [EPAP or PEEP]

IPAP = PS + [EPAP or PEEP]

Flow curve

Points of interest

Expiratory Trigger:

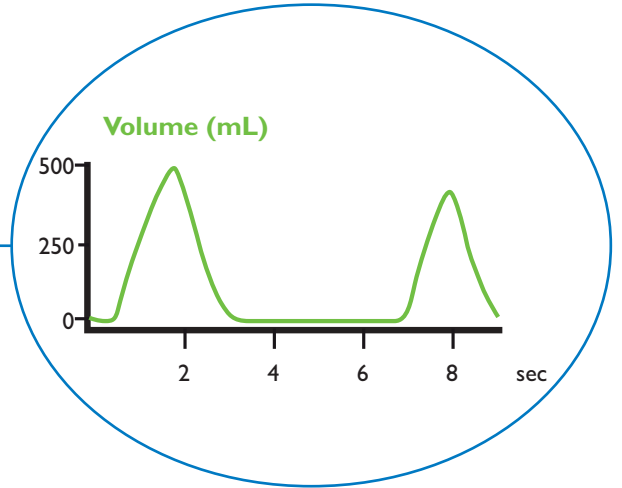

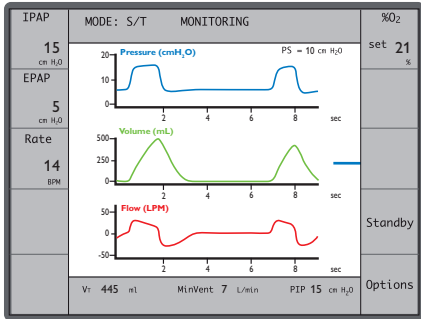

- % of Inspiratory peak flow
or
- Absolute value in LPM
or
- Set inspiratory time ($=T_i$)

T_i : Inspiratory time

T_e : Expiratory time

T_{tot} : Total breath time

$$T_{tot} = T_i + T_e$$

Volume curve

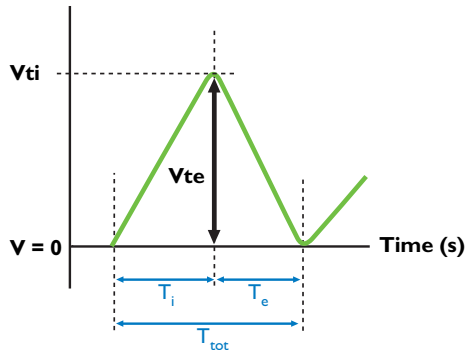

Points of interest

No leak
 $V_{ti} = V_{te}$

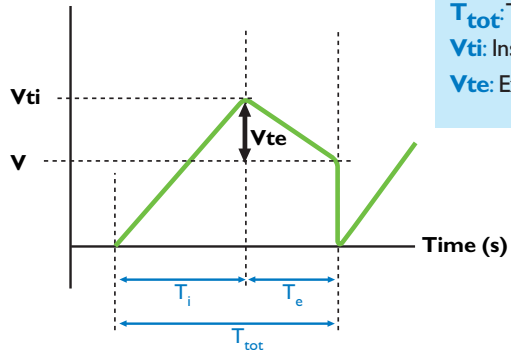

$$V_{te} = V_{ti} - V$$

Leak
 $V_{ti} > V_{te}$

Volume (mL)

Volume (mL)

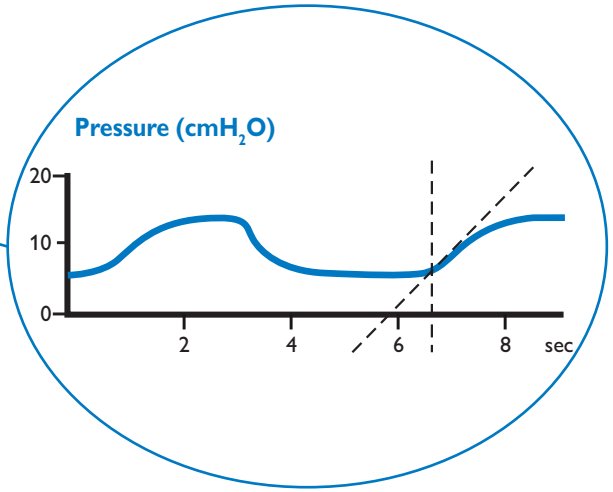

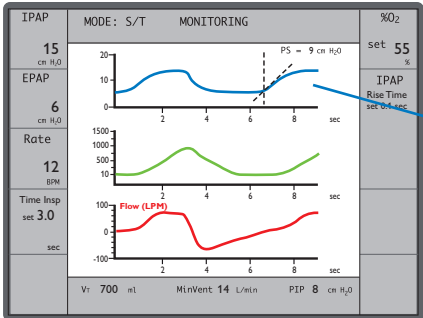

T_i : Inspiratory time

T_e : Expiratory time

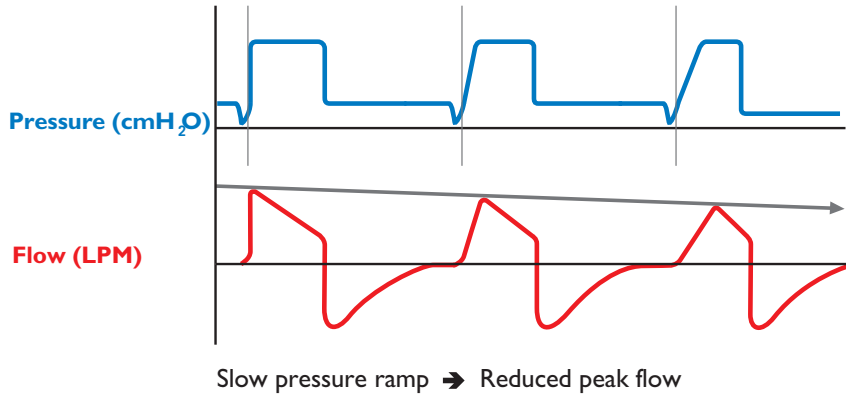

T_{tot} : Total time $T_{tot} = T_i + T_e$

V_{ti} : Inspiratory total volume

V_{te} : Expiratory total volume

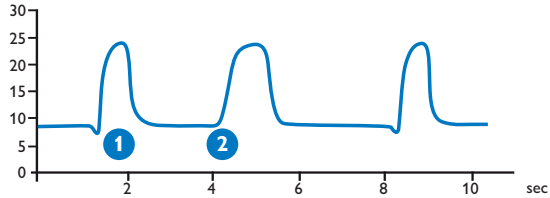

Pressure ramp ▼ Flow impact

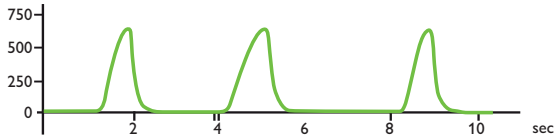

Auto triggering

Pressure (cmH₂O)

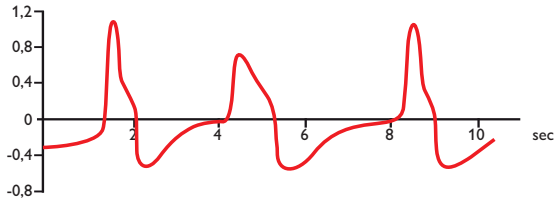

- 1 Breath normally triggered
- 2 Auto-triggered breath

Volume (mL)

Flow (LPM)

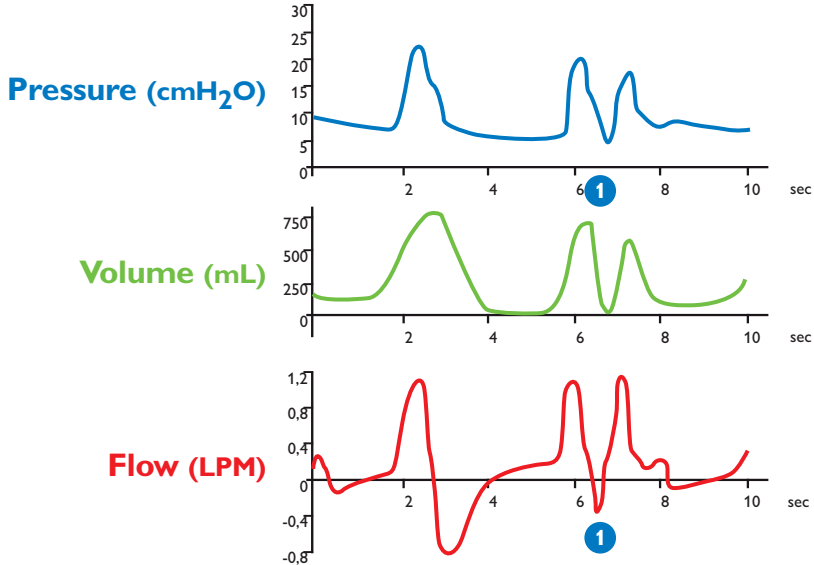

Auto triggering

Breath number 2 is triggered in the absence of patient's inspiratory effort (no abrupt decrease in pressure). This does not represent an automatic change to backup mode.

Autotriggering can occur:

- leakage
- mobile condensation in the circuit
- trigger too sensitive

Double triggering

1 Double triggering

Double triggering

Double triggering defined as two consecutive ventilator cycles separated by an expiratory time less than one-half the mean inspiratory time*.

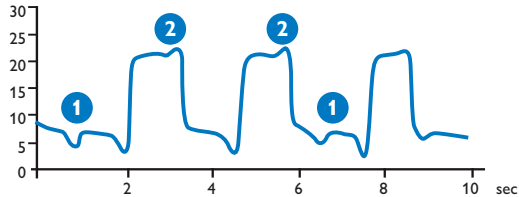

Double triggering can occur:

- ventilator inspiratory pattern ...
- patient's effort ...
- ventilator settings (insp. time, cycling criteria, ...)

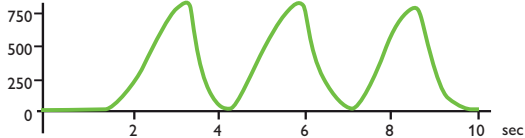

*Thille et al: Patient-ventilator asynchrony during assisted mechanical ventilation. Intensive Care Medicine (2006) 32:1515-1522

Ineffective triggering

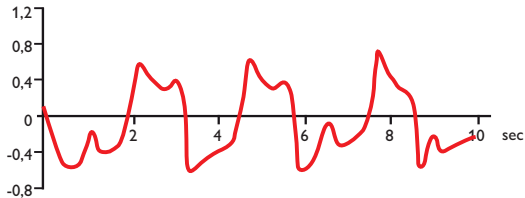

Pressure (cmH₂O)

Volume (mL)

Flow (LPM)

- 1 Inspiratory ineffective triggering
- 2 Expiratory ineffective triggering

Ineffective triggering

A wasted effort is defined as an airway pressure drop simultaneous to a flow increase not followed by a ventilator cycle*.

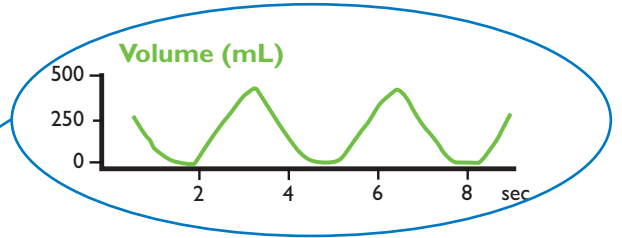

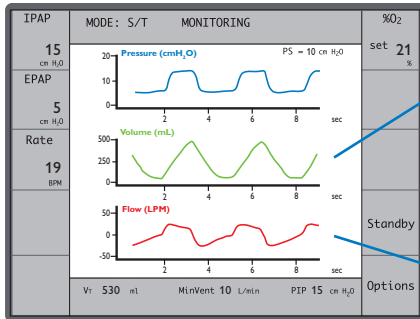

Due to patient's active expiration an increase in pressure was not recognized as end inspiration.

Ineffective triggering can occur:

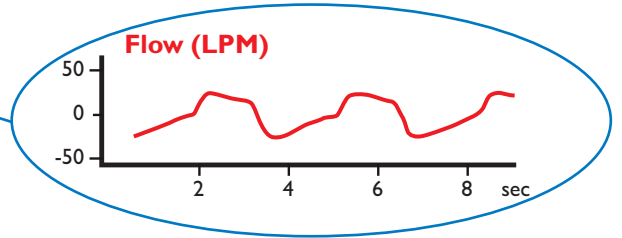

- patient respiratory system mechanics
- inadequate setting (insp trigger, cycling criteria, ...)
- excessive inspiratory support

* Thille et al: Patient-ventilator asynchrony during assisted mechanical ventilation. Intensive Care Medicine (2006) 32:1515-1522

No leakage

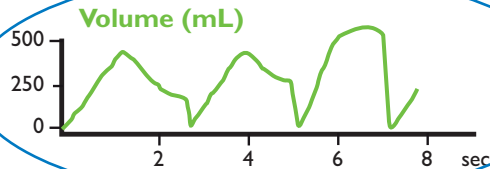

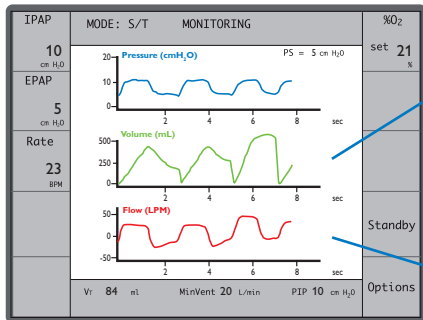

- End of expiratory volume reach 0 value

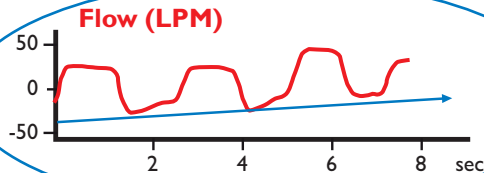

- Flow curve present no leakage readjustment

Leakage

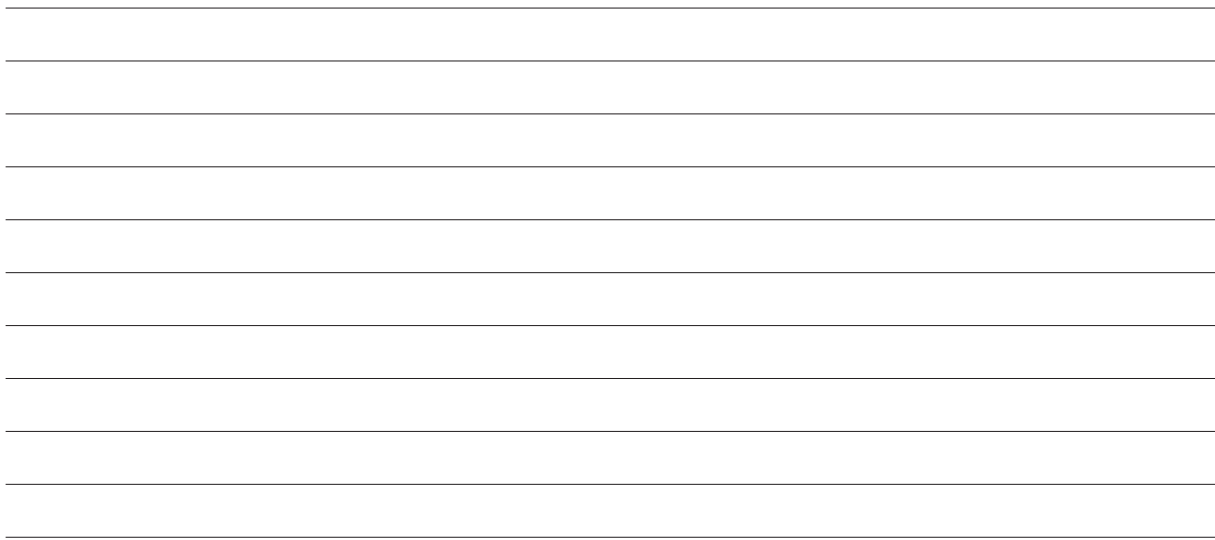

- **Volume curve drop suddenly to 0 when breath is triggered**

- **Base line flow is different than 0 during leakage readjustment**
